Abstract: This paper presents a linear 1 × 2 “Ha (τηπ)”–slot patch array microstrip antenna. The proposed design of an array microstrip antenna is intended for Wireless Local Area Network (WLAN) 2.4 GHz devices. From the previous research concerning the single patch “Ha (τηπ)”–slot microstrip antenna, the gain that can be achieved is 5.77 dBi in simulation. This value is considered too small for an antenna to accommodate WLAN devices if compare to a Hertzian antenna. To enhance the gain of microstrip antenna, some methods can be considered using linear 1 × 2 patch array and T-Junction power divider circuit to have matching antenna impedance. The distances between two patches are one of the important steps to be considered in designing the patch array microstrip antenna. Thus, the minimum distance between the patch elements are calculated should be greater than λ/2 of the resonance frequency antenna. If the distance less than λ/2 electromagnetically coupled will occur, vice versa when it is to widen the dimension of the antenna will less efficient. Epoxy substrate Flame Resistant 4 (FR4) with dielectric constant 4.3 is used as the platform designed for the array antenna and it is analyzed using simulation software Computational Simulation Technology (CST) studio suite by which return loss, Voltage Standing Wave Ratio (VSWR), and gain are calculated. The simulation result showed that the designed antenna achieve return loss (S11) -25.363 dB with VSWR 1.1 at the frequency 2.4 GHz, and the gain obtained from simulation is 8.96 dBi, which is greater than 64.4 % if compared to the previous one. The proposed antenna design shows that increasing the number of patches in the array can technically improve the gain of a microstrip antenna, which can cover a wider area if applied to WLAN devices.

Keywords: CST Studio Suite, Flame Resistant 4, Return Loss (S11), T-junction, Voltage Standing Wave Ratio.

1. INTRODUCTION

Antenna can be classified as the transducer, which is able to transfer energy from one form to another [1–3]. From this meaning, the antenna has a very important role in wireless telecommunication, because the antenna is a metal conductor that can radiate and harvest radio waves [4]. Along with the rapid development of wireless communication devices, the need for an antenna in a small size, compact, lightweight, and the ability to work in a wide band frequency is required. One type of antenna which suitable for this requirement is a microstrip antenna [5]. Besides some advantages possessed by microstrip antenna, there are also disadvantages such as poor efficiency, narrow bandwidth, and low gain, which becomes a major problem for mobile communication designers [6]. From previous research on the single patch “Ha (τηπ)”-slot microstrip antenna, the gain obtained is 5.77 dBi for simulation, and the gain from the antenna after fabrication and measurement it reaches only 3.576 dBi [7]. This value is relatively low if compared to other types of antenna such as Hertzian antenna [8]. To accommodate WLAN devices, the gain of the single patch microstrip
antenna should be improved, thus it can operate in the 2.4 GHz frequency and can cover a wider area [9]. Some considerable methods and techniques can be used to overcome this problem. One method that has been utilized to improve the gain of microstrip antenna is the patch arrangement in an array [10]. An antenna array is a combination of several connected antennas arranged to form a single antenna [11]. The main benefits of array microstrip antenna are the increase of overall gain, providing reception of diversity, and interference canceling from a common set of directions [9].

In this research a linear $1 \times 2$ “Ha (\text{nm})”-slot patch array microstrip antenna is designed and simulated, as the development and improvement of a single patch “Ha (\text{nm})”-slot microstrip antenna [7]. Thereafter, the design was simulated using CST studio suite student version software to have the result of return loss (S11), VSWR, and antenna gain.

2. MATERIALS AND METHODS

2.1 “Ha (\text{nm})”-slot Microstrip Antenna

The linear $1 \times 2$ “Ha (\text{nm})”-slot patch array microstrip antenna is designed to work for frequency 2.4 GHz. This frequency is an ISM (Industrial, Scientific, and Medical) which is not regulated and can be freely used [12]. Material parameters for the simulation are set for the dielectric substrate FR4, which has the dielectric permittivity constant ($\varepsilon_r$) = 4.3 and the substrate thickness (h) = 1.5 mm.

The basic design of the linear $1 \times 2$ “Ha (\text{nm})”-slot patch array microstrip antenna is based on a single patch “Ha (\text{nm})”-slot microstrip antenna, which can be shown in Figure 1 [7].

The dimension and annotation of the single patch microstrip antenna can be explained in the Table 1 [7].

2.2 Patch Array Microstrip Antenna Design

Based on the single patch “Ha (\text{nm})”-slot microstrip antenna design, the “Ha (\text{nm})”-slot patch array was developed in a corporate feed network. The design of the two-element microstrip patch array antenna with the “Ha (\text{nm})”-slot can be shown in Figure 2.

In order to achieve the design shown in Figure 2, three steps need to be carried out. Namely, obtaining the distance between two patches, the width dimensions, and the length of the microstrip antenna patch array two-element.

The first step is to determine the distance between patch array elements. The minimum distance between the elements for the patch array is $\lambda/2$ of the resonance frequency antenna in Equation (1) [13].

\[ d = \lambda/2 = \frac{v}{(2 \times f)} \]  

Where $d$ is the distance between patches, $v$ is the velocity of light in free space ($3 \times 10^8$ m s$^{-1}$), and $f$ is the resonance frequency of the antenna.

The estimation of the minimum distance between elements is due to the effect of electromagnetically coupled which occurs if the distance between elements is less than $\lambda/2$. However, the microstrip antenna substrate dimension will result in less efficiency if the distance is too wide.

The second step is to determine the width of the ground plane ($W_g$) microstrip patch array antenna of two elements. The $W_g$ can be calculated by Equation (2):

\[ W_g = (2 \times c) + (2 \times W_p) + d \]  

Where $W_p$ is the width of the patch, $c$ is the distance between the edge of the substrate and the patch, and $d$ is the distance between patches.

The third step is to determine the length of the ground plane ($L_g$). The $L_g$ can be calculated with the consideration of the T-Junction dimension in Equation (3). To ease the calculations of dimension T-Junction, notation #1 to #6 is added, which is shown in Figure 2.

\[ L_g = a + L_p + d' + L_{s5} + (L - 0.6955) \]  

Where $a$ is the distance between the edge of the upper side of the microstrip antenna and the patch, $L_p$ is patch length which both of them have the same length, $d'$ is the length of the microstrip feed line which has an impedance of 50 $\Omega$, $L_{s1}$ and $L_{s5}$ are the T-junction lengths of the power divider and
matching impedance and 0.6955 (mm) is the width difference between \( L_{ae} - L_{a2} \) or \( L_{ae} - L_{a3} \) because the width of \( L_{a2} \) and \( L_{a3} \) are equal.

### 2.3 T-Junction Power Divider

T-Junction is a method to connect the two patch microstrip antenna as a radiating element arranged in a row (corporate feed). The utilization of the T-Junction power divider method as a feeder and signal distributor to both patches is on the simplicity of matching by adjusting the position of the inset feeding and it is relatively easy to model it [14]. Figure 3 shows the standard form of the T-Junction power divider [14].

From the T-Junction design shown in Figure 3, the procedure to obtain the dimensions of the microstrip feed line for Power Divider are as follows:

i. For designing two-element array or \( 1 \times 2 \) patch array microstrip antenna arranged incorporate feed, a power divider is needed to connect the two elements of the microstrip antenna array with a transmission line, which generally has a 50 \( \Omega \) impedance. To calculate both impedance matching can be obtained using Equation (4) [15].

\[
Z = Z_0 \times \sqrt{N}
\]  

(4)
corporate feed.

The utilization of the T-Junction power divider is relatively easy to model it \([14]\). Figure 3 shows the T-Junction power divider.

Where \(Z\) is the required impedance value according to the number of microstrip antenna element arrays, \(Z_0\) is the input impedance of the microstrip \((Z_m)\) antenna, and \(N\) is the number of elements or arrays of microstrip antennas.

### ii. After the value of \(Z\) is obtained, the next step is to calculate the dimensions of the microstrip line input impedance \(Z_m\). The width \((W)\) and length \((L)\) of the microstrip line 50 \(\Omega\) can be calculated. Start calculating the susceptance \((B)\) \([2]\) of the microstrip line using Equation (5).

\[
B = \frac{(60 \times \pi^2)}{(Z_0 \times \sqrt{\varepsilon})}
\]  

(5)

Where \(B\) is the value of susceptance, \(\pi\) is a constant value of 3.14, \(Z_0\) is the impedance of the transmission line and the 50 \(\Omega\) antenna channel \((Z_m)\) and \(\varepsilon\) is the relative permittivity of the substrate material of the antenna.

### After calculating the value of \(B\), the next step is calculating the width \((W)\) \([4]\) of the power divider by using Equation (6).

\[
W = \frac{2h}{\pi}\left[B - 1 - \ln(2B - 1)\right] + \frac{1}{2}\left[\frac{1}{\varepsilon} + \frac{1}{\varepsilon_0}\right]
\]

(6)

### iii. Length \((L)\) of impedance 50 \(\Omega\) microstrip line can be obtained with Equation (10). However, before calculating the length of the microstrip line 50 \(\Omega\), the ratio of the width microstrip feed line to the thickness of the substrate \((W/h)\) should be examined by Equation (7) \([4]\).

\[
W/h > 1
\]

If the requirement of \(W/h > 1\) is met, then the dielectric constant value \((\varepsilon_d)\) can be calculated using Equation (7) as follows \([24]\).
\[ \varepsilon_{\text{eff}} = \frac{(\varepsilon_r + 1) + (\varepsilon_r - 1)}{2} \frac{1}{\sqrt{1 + 12 \frac{\varepsilon_r}{\varepsilon_{\text{eff}}}}} \]  
(7)

As a result of the microstrip antenna effective area, the effective wavelength of the antenna is obtained using Equation (8):

\[ \lambda_0 = \frac{v}{f} \]  
(8)

Where, \( v \) is the velocity or speed of light in free space \( (v_o) \) \( 3 \times 10^8 \text{ m s}^{-1} \) and \( f \) is the resonance or operating frequency of the antenna in units (Hz) or cycle per second (c s\(^{-1}\)).

Moreover, the effective length (\( \lambda_0 \)) of the microstrip antenna can be obtained by Equation (9).

\[ \lambda_0 = \frac{\lambda}{\sqrt{\varepsilon_{\text{eff}}}} \]  
(9)

Finally, the length (\( L \)) of the microstrip feed line can be calculated in Equation (10) with an impedance of 50 \( \Omega \). The effective length of the antenna is a quarter lambda (\( \lambda/4 \)) of the effective wavelength, according to Equation (10).

\[ L = \frac{\lambda_0}{4} \]  
(10)

The microstrip line 70.7 \( \Omega \) can be obtained using the calculation in step 2 and step 3.

### 2.3 Proposed Antenna

The proposed design of the linear 1 × 2 “Ha (\( \lambda/\pi \))”-slot patch array microstrip antenna is shown in Figure 4.

The calculation results obtained for ground plane length (\( L_g \)) as follows:

\[ L_g = 15 + 18 + 15 + 17.2915 + (17.715 - 0.6955) = 82.311 \text{ mm} \]

The width of the ground plane (\( W_g \)) is obtained as follows:

\[ W_g = (2 \times 45) + (2 \times 38.3934) + 62.5 = 229.286 \text{ mm} \]

The dimension of Figure 4 and the power divider is given in the following Table 2.

Besides the design of the patch array microstrip antenna, the antenna power divider becomes the essential part of the design. In order to have the matching impedance of both patch array microstrip antennas, it is necessary to calculate the value of the T-Junction power divider, which can be explained in four steps.

i. Determine the impedance of power divider Z. From Equation (4) the value of required impedance for two elements can be obtained. If \( Z_0 = 50 \Omega \), and the number of patch element \( N = 2 \), then the value of impedance \( Z \) is equal to:

\[ Z = 50 \times \sqrt{2} = 70.71 = 70.7 \Omega \]

ii. In this research, the relative permittivity \( \varepsilon_r \), of FR4 (epoxy) material generally varies from 4.3 to 4.4 (which then the value 4.3 is used for designed calculations) in Equation (6).

\[ B = \frac{60 \times (3.14)^2}{50 \times \sqrt{4.3}} = \frac{591.576}{103.682} = 5.706 \]

After calculating the value of \( B \), the next step is calculating the width (\( W \)) of the power divider by using Equation (6).

The FR4 thickness \( h \) of the substrate is 1.5 mm.

\[ W = \frac{2 \times 1.5}{3.14} \left( \frac{5.706 - 1 - \ln(2 \times 5.706 - 1)}{4.3} + \frac{4.3 - 1}{4.3} \right) \ln(5.706 - 1) + 0.39 - 0.61 \] \[ W = 2.92 \text{ mm} \]

iii. After the width (\( W \)) of the power divider is obtained, the next step is to examine the ratio between the width (\( W \)) and the height of the substrate using Equation (7).

\[ \frac{W}{h} > 1 \]

\[ \frac{2.92}{1.5} = 1.9467 > 1 \]

Because \( W/h > 1 \), the dielectric constant value \( (\varepsilon_{\text{eff}}) \) uses Equation (7) as follows [2]. Thus,
The design and simulation of a patch array microstrip antenna are discussed in this paper. The antenna is a corporate feed, and its performance is evaluated using CST Microwave Studio software. The simulation result for return loss (S11) at a resonance frequency of 2.4 GHz is shown in Figure 7. The antenna is designed using Flame Resistant 4 (FR4) material with a dielectric constant of 4.3. The simulation and analysis of the antenna design are presented, and the results are compared with previous designs. The antenna is suitable for use in WLAN devices and can improve the gain of a microstrip antenna, which can cover a wider area when applied. The return loss (S11) of the antenna is calculated using Equation (10), and the effective length (L) is obtained from Equation (7). The effective wavelength (λ₀) is calculated using Equation (8), and the effective area of the antenna is obtained from Equation (4). The results show that the proposed antenna design offers improved performance compared to previous designs.
for return loss (S11) patch array microstrip antenna is as low as -25.363, which means that the design of the antenna has a very small reflection or VSWR = 1.

### 3.2 Gain Antenna

In the following Figure 7, it shows the gain of the antenna.

Figure 7 above, shows that the result of gain measurement from simulation. In which the main lobe direction of the antenna is 25.0 degrees, and the maximum gain antenna is 8.96 dBi.

Therefore, the simulation comparison between a single “Ha ( )”-slot patch and 1 × 2 “Ha”-slot patch array microstrip antenna is shown in Table 3.

4. DISCUSSION

This research discusses the design and simulation of linear 1 × 2 “Ha ( )”-slot patch array microstrip antenna. The simulation result can help to take the next step for fabrication. To ensure that the fabrication can be achieved successfully, calculation in designing the patch array antenna is needed. After obtaining each value parameter based on calculation and achieving the antenna dimensions, the next step is to design the antenna in CST simulation. The CST studio suite is utilized to simulate a patch array microstrip antenna to measure the return loss (S11) and antenna gain.

In designing the patch array microstrip antenna, there are two critical parts that need to be considered and optimized. The first part is the distance between two array patches, which should be no less than λ/2 of the resonance frequency antenna. And then the next part is the T-Junction power divider, which will determine the impedance of both patch array.

5. CONCLUSION

A linear 1 × 2 “Ha ( )”-slot patch array microstrip antenna is designed and simulated. The simulation’s result shows that the patch array configuration can achieve return loss (S11) -25.363 dB with VSWR 1.1 at the frequency 2.4 GHz and the value for gain can reach 8.96 dBi. Hence, the result of the gain in patch array increased by 64.4% if compared to the gain value of the single patch “Ha ( )”-slot microstrip antenna.
